1. THE ROLE OF GENETIC VARIABILITY IN EVOLUTION 3

Problems raised by Darwin and his contemporaries about the nature of inherited variation remain unanswered at the present time

Darwin and variability 3
Simple models of population structure espoused by the early Mendelians 5
Does evolution proceed by saltations? 6
The role of natural selection 11

2. NEUTRALISM *V.* SELECTION 13

The controversy between 'neutralists' and 'selectionists' is an old one, and is unlikely to be resolved in the near future

The consequences of having many neutral alleles in a population 13
Selection and drift before 1966 15

3. ARGUMENTS FOR AND AGAINST POSTULATING A LARGE CLASS OF NEUTRAL GENES 22

It is shown that the need for postulating a large class of selectively neutral genes is, at least in part, a function of the assumptions made about the nature of genetic variability

The magnitude of the substitutional load 22
The magnitude of the segregational load 32
The decrease of fitness from inbreeding 43
The constancy of rates of molecular evolution 45
The distribution of allele frequencies as an indicator of selection or neutrality 57
Neutrality *v.* selection or purifying *v.* balancing selection? 66

4. NEW MOLECULAR EVIDENCE FOR SELECTION **68**

Selection must be more powerful than conventional population-genetics theory permits if it is to influence all parts of the genome

The evolution of molecular function 68
Untranslated and degenerate regions of the genome 79
Other evidence for the action of selection on untranslated regions 90

5. EVIDENCE FOR BALANCING SELECTION **92**

A great variety of selective mechanisms have been found or inferred to be responsible for the maintenance of human polymorphisms. One important mechanism for which there is no evidence is unconditional heterozygote advantage

Cases of conditional single-gene heterozygote advantage 92
Polymorphisms in which heterozygote advantage is not certain 104
Polymorphisms for which balancing selection can be inferred, although a clearcut mechanism cannot be implicated 113
Summary 133

6. MATCHING MODES OF SELECTION TO CLASSES OF VARIABILITY **137**

Alleles with pronounced selective effects are likely to show rather limited interaction with the environment, and to be acted upon by multiplicative or approximately multiplicative selection. Those with much smaller effect will both be more numerous and more likely to be acted on by truncation or quasi-truncation

A classification of the types of genetic variability subject to selection 137
Fitness potential and rank-order selection 141

7. THE NATURE OF BALANCED GENETIC VARIABILITY **159**

The distribution of polymorphisms subject to conditional heterosis and marginal overdominance may be very different from that expected from unconditional heterosis, and may mimic that of neutral alleles. Such modes of selection will be missed by the design of most population genetics experiments

What kinds of balancing selection are possible? 160
Information from quantitative genetics on the nature of genetic variability 182
Heritability, genotype–environment interactions, and viability measurements 195

Some possible examples of marginal overdominance at single loci in drosophila 209
Do diverse environments allow more genetic variability to be retained? 213

8. THE CONDITIONS UNDER WHICH THE GENE IS THE UNIT OF SELECTION 217

The problem of associative overdominance in the interpretation of population genetics experiments is shown to be minimized in a large outbred population. Under these conditions associations between loci resulting from linkage can be shown to be small and primarily due to sampling. The sampling effect is demonstrated for the human MNSs and Rh loci. Experiments are suggested which take advantage of this phenomenon

Linkage disequilibrium and the interpretation of population genetics experiments 218
How linkage can influence the genome 221
The theory of the crystallization process 227
Predicting the results of simulations 231
The conditions for crystallization 234
The pattern of disequilibria to be expected from sampling 238
Data from humans illustrate the influence of allele frequency on sampling disequilibrium 243
Linkage disequilibrium and associative overdominance 248

9. THE EVOLUTION OF RECOMBINATION 254

The contrasts between selection in which the fitness is determined directly by the genotype and selection in which it is determined only indirectly by the genotype are explored. It is suggested that for most of the cases investigated the former gives a selective advantage to reduced rates of recombination between loci, while the latter gives a selective advantage to increased rates of recombination

The essence of Fisher's problem 255
Mechanisms that reduce the variance of the selected character 256
How truncation selection provides an advantage to recombination 263
The results of computer simulations 264
