Acknowledgments xix

1

Introduction

The Plant Body 4
 The Vascular System of Land Plants 5
 Meristems 9
 Roots 12
 Stem 15
 The Vascular Cambium and Secondary Growth 15
 Leaves 19
Differences between Plants and Animals as Organisms 24
 Mechanisms for Obtaining Food and Other Nutrients 24
 Reproductive Mechanisms 24
 Plants do not establish a germ line 24

<i>Plants reproduce asexually as well as sexually</i>	25
<i>Sexuality is not as well defined in plants as it is in animals</i>	25
<i>The plant life cycle is more elaborate than that of animals</i>	27
Survival Mechanisms	29
<i>Plants and animals use different strategies to protect against adverse environmental conditions and invading microorganisms</i>	29
Differences in the Developmental Mechanisms of Plants and Animals	30
Postembryonic versus Embryonic Development	30
Nature of Cell Commitment for Differentiation	31
Fate of a Plant Cell as Determined by Its Position in the Organism	32
Brief Developmental History of a Typical Flowering Plant	32
Model Systems for the Analysis of Plant Development	34
Summary	37
Questions for Study and Review	39
Further Reading	40

2

The Genetic Basis of Plant Development

Mendel and the Laws of Heredity	41
Hammerling's Work on <i>Acetabularia</i>	44
Regeneration after Wounding	46
Grafting of Parts of Different <i>Acetabularia</i> to Each Other	47
Information Flows from the Nucleus to the Cytoplasm via Messenger RNAs	48
Gene Linkage	49
Chromosome Structure	49
Distribution of Chromosomes to Daughter Cells in Cell Division	50
Linkage Maps	50
Genetic Control of Developmental Characteristics	54
Phenotypic Consequences of a Change in the Expression of a Single Gene	58
Identification of Genes through Mutations	59
Genetic Control of Developmental Processes	62
Synthesis of Anthocyanin Pigments	62
Developmental Regulation of Anthocyanin Synthesis	64
Transposons	65
Identification of Key Regulatory Genes through Homeotic Mutations	67
Role of Differential Growth in Plant Development	72
Summary	74
Questions for Study and Review	76
Further Reading	77

3**The Size and Complexity of Plant Genomes**

- The Structure of DNA and RNA 80
- The Structure of Proteins 83
- The Genetic Code 87
- Plant Nuclear Genomes 87
 - Amount of DNA in Plant Nuclear Genomes 87
 - Chromatin Structure 95
 - Number of Genes Required to Encode the Functions of an Angiosperm 95
 - Important Proteins Encoded by Multigene Families 99
 - Correlation of Genome Size with Organismic Complexity 99
 - Polyploidy 100
 - Repetitive-Sequence DNA 103
 - Fraction of DNA Containing Functional Genes 108
 - Repetitive DNA 108
 - Location of Repetitive DNA in Plant Genomes 109
 - Chromosomal Localization of Satellite DNAs 110
 - Heterochromatin is a portion of the nuclear DNA that remains condensed in interphase 111*
 - Repetitive-sequence DNA could be involved in speciation 112*
- Transposons 113
 - Transposons and Mutations 114
 - Transposons of Maize 117
- Viruses 119
 - Retroviruses 122
 - Vertebrate Tumor Retroviruses 125
 - The Reverse Transcriptase Gene in Cauliflower Mosaic Virus 126
 - Retrotransposons 126
 - Nonviral Retrotransposons 128
- Genomes of Chloroplasts and Mitochondria 130
 - Plastids 132
 - Chloroplast Genomes 132
 - Mitochondrial Genomes 135
- Recombinant DNA Methods in the Analysis of Plant Genomes 136
 - Bacterial Plasmids 138
 - Nucleases as Tools in Molecular Biology 139
 - Reintroduction of Cloned Genes into Plants by *Agrobacterium*-Mediated Transformation 143
 - Regeneration of Plants from Transformed Cells 144
 - Other Procedures to Introduce DNA into Monocots 145
 - Reporter Genes 145
- Summary 146
- Questions for Study and Review 149
- Further Reading 150

4

Regulation of Gene Expression

- Control of Gene Expression 154
- Gene Structure 155
- Structure of Messenger RNA 156
- RNA Processing 156
- Transcription of Genes by RNA Polymerases 158
 - Negative Control 158
 - Positive Control 159
 - Control of Gene Transcription in Bacteria 159
- Regulation of Bacteriophage Gene Expression by DNA-Binding Proteins 162
 - The Lambda Repressor 164
 - Study of DNA-Protein Interaction by "Footprinting" 165
 - Binding of Lambda Repressor to 17-bp Sequence within Operator Region 165
 - Binding of Cro Protein Operator 170
 - Helix-Turn-Helix Structure in Lambda Repressor and Cro 170
- Control of Transcription in Eukaryotes 174
 - Transcription of DNA in Eukaryotes by Three Different RNA Polymerases 175
 - TATA-Binding Protein and the TATA Box 176
 - Viral Transcription 178
 - Role of Enhancers in Regulating Gene Expression 178
 - Regulatory Signals Controlling Expression of the CaMV 35 S Promoter 180
 - Regulatory Sequences of the 5' Upstream Sequence of the 35 S CaMV Promoter 182
 - Oncogenes Encoding Transcription Factors 185
 - Leucine Zippers 186
 - DNA-binding domains are adjacent to leucine zippers* 186
 - Some plant transcriptional regulators are leucine zipper proteins* 187
 - Steroid Hormones 189
 - Steroid hormones regulate development in animals* 189
 - Steroid hormone receptors are potential DNA-binding proteins* 189
- Summary 190
- Questions for Study and Review 192
- Further Reading 194

5

Characteristics of Plant Cells That Are Important in Development

- Membranes 198
 - Lipid Bilayer 198
 - Membrane Proteins 199
 - Division of Cell into Compartments 199

- Protein Synthesis and Protein Targeting 202
- The Golgi Apparatus 203
- Plant Vacuoles 205
- Vacuoles as Osmotically Active Compartments 206
 - Vacuoles as Lysosomes 207
 - Vacuoles as Storage Depots 207
 - Vacuoles as Depositories for Secondary Products 208
- The Cytoskeleton 208
- Microtubules 210
 - Tubulin is a highly conserved protein* 210
 - Microtubules form by a self-assembly process* 211
 - GTP hydrolysis is important for tubulin assembly–disassembly* 213
 - Microtubule organizing centers determine where microtubules are formed in cells* 215
 - Plant microtubules often are cold stable* 216
 - Some plant secondary products affect microtubule assembly* 216
 - Microtubule motors are responsible for many types of intracellular transport* 218
 - Actin and Microfilaments 218
 - Microfilaments are composed of actin protein subunits* 218
 - Higher plant actins are similar to the actins of other organisms* 220
 - G-actin can self-assemble to form microfilaments* 221
 - Proteins bind to actin filaments and regulate their formation and function* 223
 - Myosins are microfilament motor proteins* 223
 - Capping proteins bind to actin filament ends* 227
 - Intermediate Filaments 229
 - Cytoskeletal Arrays of Plant Cells 229
 - A cytoskeleton is present in most interphase cells* 230
 - Radial array microtubules are initiated from the nucleus* 232
 - A preprophase band is formed before cells enter into mitosis* 233
 - The mitotic spindle begins to form in prophase when the nucleus is still surrounded by radial array microtubules* 237
 - The phragmoplast constructs the cell wall that will partition the cytoplasm and separate the two daughter nuclei of the dividing cell* 239
- Plant Cell Walls 241
- Cell walls are composed mainly of polysaccharides* 244
 - Cellulose is a simple, linear polymer of glucose subunits* 245
 - Noncellulosic polysaccharides are heterogeneous in composition* 245
 - Structures of several sycamore cell wall noncellulosic polysaccharides have been determined* 248
 - Primary cell walls also contain proteins* 248
 - Wall polymers are interconnected in the cell wall matrix* 250
 - Noncellulosic cell wall polysaccharides are synthesized by the Golgi apparatus and transported to the wall in vesicles* 250
 - Secondary walls differ from primary walls in composition and structure* 251
 - Cellulose microfibrils may be oriented in primary walls* 254
 - How are cellulose microfibrils synthesized and deposited?* 255
 - Usually the most recently deposited cellulose microfibrils tend to be aligned in primary cell walls* 255

Cortical microtubules can control the orientation of cellulose microfibril deposition 260

Cell–Cell Communication and Intercellular Transport in Plants 261

Summary 264

Questions for Study and Review 266

Further Reading 268

6

Light, Hormones, and Cell Signaling Pathways

Light 274

Light versus Darkness 274

Chloroplast Development 274

Ribulose-1,5-bisphosphate Carboxylase–Oxygenase (RUBISCO) Gene Expression 280

Regulation of RUBISCO gene expression is complex 280

RUBISCO gene expression is regulated by light and development 281

Transcription of rbcS genes is regulated by a complex interaction of transcription factors with each other and with regulatory elements in the promoters of these genes 283

Mediation of Photomorphogenic Responses by Three Light Receptors 286

Phytochrome exhibits two interconvertible light-absorbing forms 288

Most plants probably have several different phytochromes 291

Mutations affect phytochrome responses 294

Phytochrome regulates the expression of nuclear genes 297

Hormones 298

Auxin 299

Auxin was the first plant hormone to be identified 299

The auxin biosynthetic pathway is not known with certainty 301

Auxin regulates many aspects of plant growth and development 303

Gibberellins 304

Gibberellins have an unusual chemical structure that is not closely related to any primary metabolite 306

Gibberellins regulate stem elongation 306

Cytokinins 311

Some bacteria secrete cytokinins 311

Cytokinin biosynthesis involves the mevalonate pathway 313

Where are cytokinins synthesized in higher plants? 313

How is cytokinin transported and metabolized? 315

Cytokinins regulate many aspects of plant growth and development 315

Abscisic Acid 317

Abscisic acid synthesis may be regulated by stress and photoperiod 317

<i>Abscisic acid induces stomatal closure</i>	319
<i>Gene expression is regulated by abscisic acid</i>	319
Ethylene	320
<i>Ethylene is derived from the amino acid methionine</i>	320
<i>Ethylene production varies in different plant tissues</i>	322
<i>Ethylene synthesis can be induced</i>	322
Initiation of Regulatory Cascades by Hormones	323
Signal Transduction in Response to Insect Attack	323
Calcium Ion Regulation of the Activity of Some Protein Kinases	326
Calmodulin Requirement for Many Calcium Ion-Induced Responses	329
Inositol Phosphates and 1,2-Diacylglycerol as Important Second Messengers	331
Key Role of Membrane-Associated G Proteins in Signal Transduction Pathways	331
Summary	335
Questions for Study and Review	337
Further Reading	338

7

Cell Division, Polarity, and Growth in Plant Development

The Cell Division Cycle and Its Control	342
The Two Control Points in the Cell Cycle	342
<i>Proteins known as cyclins trigger the start of the cell cycle and initiate mitosis</i>	343
<i>The G1 regulatory point known as Start controls entry into the S phase of the cycle</i>	343
<i>Yeasts have provided important insights into how a cell's progression through its cell cycle is controlled</i>	344
<i>Conditional mutations have identified specific genes whose products are required for progression through the cell cycle</i>	345
<i>The cdc2 gene product is necessary for Start and for entry into mitosis</i>	347
<i>Cell division is regulated during plant development</i>	349
Division in Differentiated Plant Cells	352
<i>Diffusible factors control plant cell division</i>	352
<i>Plant tissues and organs can be cultured</i>	353
<i>Hormones may regulate the plant cell cycle</i>	353
Role of Cell Division in Plant Development	354
Contribution of Cell Division to Plant Development	354
Formative Divisions	354
Unequal Cell Divisions	359
Perpetuation and Loss of Determined States	359
Polarity	363
Establishment of Polarity before Elongation	364

Cell Enlargement and Its Hormonal Regulation	370
The Cytology and Physiology of Plant Cell Enlargement	371
Target Tissues and Passive versus Active Growth	372
Auxin Receptors	374
Turgor Pressure and Cell Elongation	374
<i>The physical properties of the cell wall control elongation</i>	378
<i>Cell wall is synthesized during growth</i>	379
<i>Does new wall synthesis result in a change in the physical properties of the cell wall?</i>	379
<i>Auxin-induced cell wall plasticization appears to involve the hydrolytic cleavage of hemicelluloses that are linked to the cellulose microfibrils</i>	381
<i>H⁺ ion excretion weakens the cell wall</i>	382
<i>Auxin induces gene expression</i>	384
<i>How does auxin stimulate stem elongation?</i>	386
Summary	387
Questions for Study and Review	390
Further Reading	391

8

Embryogenesis, Seed Development, and Germination

The Plant Life Cycle	396
Alternation of Generations	398
Life Cycle of a Fern	400
Life Cycle of an Angiosperm	402
<i>The male gametophyte forms within the anther</i>	402
<i>The female gametophyte forms within the ovule</i>	407
<i>Pollination is the transfer of pollen from a stamen to an ovule</i>	407
<i>Pollen tubes grow only at their tips</i>	411
<i>Many higher plants are self-incompatible</i>	411
<i>Angiosperms exhibit double fertilization</i>	418
Embryogenesis and Seed Formation	418
Embryogenesis	421
<i>The origin of the different tissues and organs of the seedling plant can be traced to specific cells early in embryogenesis</i>	428
<i>Endosperm is formed in gametic embryogenesis</i>	428
<i>The endosperm and suspensor contribute to embryogenesis</i>	429
<i>Somatic cells of many plants undergo embryogenesis in special circumstances such as tissue culture</i>	431
Embryogenesis and Seed Development	432
Gene Expression during Embryogenesis	433
<i>Quantitative changes occur in gene expression during embryogenesis</i>	434

<i>How are the genes responsible for the embryogenic program identified?</i>	434
<i>Nine genes have been identified that function in determining the major events of embryogenesis</i>	437
<i>An Arabidopsis gene responsible for cotyledon differentiation has been identified</i>	439
Seed Storage Proteins	441
<i>Storage proteins are synthesized on the rough endoplasmic reticulum and deposited in protein bodies</i>	442
<i>Maize storage proteins are prolamines known as zeins</i>	443
<i>Seed storage proteins are encoded by several different multigene families</i>	443
<i>Gene transfer experiments have been useful in understanding how seed storage protein gene expression is regulated</i>	444
Seed Dormancy	445
Seed Germination	446
<i>Germination is triggered simply by imbibition of water in many plants</i>	446
<i>Early seedling growth is dependent on metabolizable substrates stored in the seed</i>	447
<i>Seeds contain stored food reserves</i>	447
<i>Hormonal signals regulate the synthesis and secretion of hydrolytic enzymes by the aleurone</i>	447
<i>Synthesis and secretion of these hydrolases require the development of ER in aleurone and this also is gibberellin-dependent</i>	447
<i>Gibberellin and abscisic acid act in the regulation of α-amylase synthesis by barley aleurone cells</i>	448
<i>Expression of the α-amylase genes is regulated at the transcriptional level</i>	449
Summary	451
Questions for Study and Review	454
Further Reading	455

9

Apical Meristems and the Formation of the Plant Body

The Shoot Apical Meristem	460
The Root Apical Meristem	464
Meristems with a Single Apical Cell	466
Repetitive Activity of Vegetative Meristems	468
Formation of Leaves	468
Apical Initial Cells, Stem Cells, and Cell Lineages	471
Concept of the Stem Cell	471
Apical Initial Cells	471
Determinant Meristems	473
Indeterminate Meristems	473
Chimeric Meristems	475

Cell Differentiation and Cell Lineage	476
Determinant versus Indeterminate Development	479
When Does a Meristem or Primordium Become Determined?	479
Changing the State of Meristems	481
Gene Expression Regulating Meristem Function	481
Genes Expressed in Meristems	485
Determination of Cell Fate in the Functioning Meristem	485
Homeodomain Proteins Determining Cell Fate	487
Flowering	489
Developmental Regulation of Floral Evocation	489
Juvenility and Phase Change in Floral Evocation	490
Environmental Control of Floral Evocation	494
Phytochrome Control of Signal That Induces Floral Evocation	495
Floral Differentiation	497
Inflorescence and Floral Meristems	497
Initiation and Differentiation of Floral Organs	498
Mutations Affecting Floral Differentiation	500
Homeotic Mutations Affecting Floral Organ Identity	503
Homeotic Genes	506
Summary	510
Questions for Study and Review	512
Further Reading	513

10

Biotic Factors Regulate Some Aspects of Plant Development

Plant–Microbe Pathogenic Interactions	518
Ways in Which Pathogens Cause Disease	520
<i>Biotrophic pathogens invade living cells and feed off the nutrients therein</i>	520
<i>Necrotrophic pathogens derive nutrients from dead cells</i>	522
Resistance to Disease	522
<i>The composition of the plant cell wall changes</i>	522
<i>Pathogenic organisms may induce a hypersensitivity response</i>	524
<i>Plants may produce phytoalexins in response to pathogens</i>	524
<i>Plants may synthesize enzymes that attack the pathogen</i>	524
<i>Pathogen avirulence and host disease resistance are genetically determined</i>	524
<i>Pathogens invade a host by expressing pathogenicity genes</i>	525
Cell–Cell Communication between the Host and Pathogen	528
<i>Host-derived molecules induce the expression of pathogenicity genes</i>	528
<i>Elicitors induce the hypersensitivity response</i>	528
<i>Elicitor–receptor binding induces expression of plant defense genes</i>	529
Crown Gall and Plant Transformation	530
Crown Gall, a Plant Cancer	530

<i>Bacteria-free gall tissues will grow in culture on simple medium lacking hormones</i>	532
<i>Crown gall tissues synthesize unusual amino acids</i>	533
T-DNA	533
<i>How is the T-DNA identified?</i>	533
<i>How is the T-DNA organized?</i>	534
<i>What genetic information does T-DNA contain?</i>	535
<i>Why can the plant cell not regulate the activity of these genes or the enzymes encoded by these genes?</i>	536
<i>How is T-DNA transferred to plant cells and integrated into the host genomic DNA?</i>	540
Attachment of Agrobacteria to the Plant Cell	540
Induction of the <i>vir</i> Genes	540
<i>The T-DNA is processed</i>	541
<i>The T-strand is transferred</i>	541
<i>The host range can be determined</i>	541
The Ti Plasmid and Plant Genetic Engineering	544
Symbiotic Interactions: Legumes and <i>Rhizobium</i>	544
Chemistry of Atmospheric Nitrogen Fixation	545
Important Contributions by the Plant to This Symbiosis	545
Establishment of the Symbiosis	546
<i>The bacteria must be able to find the plant (recognition)</i>	546
<i>The bacteria must be able to penetrate the plant (infection)</i>	547
<i>The bacteria must be able to differentiate within the plant (differentiation)</i>	547
Molecular–Genetic Analysis of Nitrogen Fixation in <i>Rhizobium</i>	547
<i>Expression of <i>nif</i> and <i>nod</i> genes in the bacterium is necessary for the formation of nitrogen-fixing nodules</i>	547
<i>Specific plant gene expression also is required for the formation of nitrogen-fixing nodules</i>	551
Questions for Study and Review	553
Further Reading	555
Index	558
